The same question, step by step, in six architectures

Which film was released earlier, Little Buddha or Course for Collision?

The passages needed to answer are supplied to every system as oracle context.

SAS — *one invocation, one continuous state*

solver
read both passages, date each film, compare, answer

source: pre-final reasoning *final: the prediction*

Sequential — *planner, ordered workers, aggregator*

planner
split into two date lookups → **worker 1**
date of Little Buddha → **worker 2**
date of the second film → **aggregator**
compare and answer

audited boundary: last worker *final: aggregator*

Subtask Parallel — *planner, independent workers, aggregator*

planner
split into two date lookups → **workers in parallel**
each date found without the other → **aggregator**
compare and answer

source: partial findings *final: aggregator*

Parallel Roles — *one input, several analytical views*

solver, extractor, verifier, skeptic
the same passages read four ways, in parallel → **aggregator**
select the supported view

source: candidate oracle *final: aggregator*

Debate — *propose, revise, pick*

proposers A and B
two independent answers → **cross-revision**
each sees the other, then revises → **picker**
choose one revised answer

audited boundary: revised-candidate oracle *final: picker*

Ensemble — *sample, then aggregate*

four samples at T = 0.7
four independent answers → **aggregator**
choose among the candidates

source: candidate oracle *final: aggregator*
